ABSTRACT

Watersheds in Anambra State are characterized by wanton deforestation, indiscriminate land use patterns and poor management. The study was therefore carried out to assess the impact of these unwholesome practices on the ecological characteristics and flora development of the watershed. The study site was situated along a perennial stream which was 1490 meters long with an average width of 3 meters. The area was divided into three segments namely, head, middle and tail covering both sides (aspects) of the stream. The segments and aspects were further divided into three plots, each measuring 60 meters by 20 meters. At each segment and aspect, sampling of plant species was done using the quadrat method (2 meters by 3 meters quadrat) to determine species abundance and diversity. Soil samples at three depths (10 cm, 30 cm and 50 cm) were also collected in each segment and aspect to determine the soil pH and micro organisms. The various land use practices on the watershed were also noted by segment and aspect. The importance value index was used to determine the species abundance while Shannon Weiner index of diversity was used to determine the species diversity of the watershed. Analysis of Variance (ANOVA) and Regression Analysis were employed in data analysis. The findings of the study showed that nearly all parts of the watershed were disturbed at varying intensities through human activities ranging from wood lumbering, farming and construction. The study showed also that with respect to segment, the species diversity of the watershed was higher at the head segment (0.81) and lower at the tail segment (0.72). Also with respect to the aspect, the study revealed that the species diversity was higher towards the left aspect (0.68) than the right aspect (0.66). The study showed a negative significant relationship between land use patterns in the watershed.

Keywords: Ecological, Human Impact Assessment and Flora

INTRODUCTION

A watershed is the area of land that forms the drainage system for a stream or river. According to [1], it is that area of land, a bounded hydrologic system, within which all living things are inextricably linked by their common water courses and where, as human settled, a simple logic demanded that they become part of a community [2]. Watershed serves as an important source of water, energy and biological diversity [3]. They are also a source of such key resources as forests, agricultural products and of recreation. From a planning stand point, watershed

has been considered the most ideal unit for analysis and management of natural resources [4]. For optimal use of environmental resources in a region, integrated watershed development approach is still viewed by many to the most ideal as it happens in maintaining the ecological basis of resources utilization [4]. As a key part of the global ecosystem, watershed represents a complex and interrelated ecology of plants, animals, soil and climate [5]. Plants community represents an important biological component which

determines to a great extent the stability of the watershed. Generally, plants help to slow runoff and reduce soil compaction in watershed, allowing the better percolation of rainfall into soils and ground water, which creates better water storage for summer based flows [6]. In addition, the patterns, sizes, and composition of the vegetation can affect many wildlife species. Vegetative composition and density can reduce or prevent soil erosion. For instance, leaves and branches may intercept the falling rain and reduce the effect of rain drop splash [7]. Vegetative litter from dead leaves and the branches on the other hand builds up an organic surface that provides protection of the soil layer [8]. Equally of key element n determining watershed wellbeing is biodiversity (which is the diversity of ecological communities, species, and genetic variants). In more explicit term, species diversity represents the number of species and their evenness and this may have direct influence on watershed cover [9,10]. However, in spite of laudable significance of the watershed, recent studies have shown that many watersheds have been lost due to excessive exploitation. Various activities such as farming, fishing, forestry, construction, mining, urban development and land

pollution are some of the human activities that are negatively affecting watershed structure and stability [11]. These activities affect habitat structure, flow regime, food web and biotic interactions in the reservoir [12]. In developing countries like Nigeria, agriculture is already a leading cause of land degradation. [13], observed that while vegetation composition affects the underlying soil and other biotic components, the decline of natural forests in developing regions will continue in total loss and the disappearance of many watersheds. Industrialization, population growth and related agricultural expansion, and forest trade are the main driving forces in reducing forest covering in Nigeria [4]. Meanwhile, while human activities may have aadverse effect on the stability of the watershed, lack of scientifically based assessments of the functional effects of land use practices on the biodiversity and soil properties of the watershed is already constraining effort aimed at conserving and managing the watershed. The main objective of this study is to examine the ecological characterization and human impact assessment on the flora of a watershed (Imo Awka River) in Awka, Anambra State.

METHODOLOGY

Six plots measuring 20 meters by 60 meters were delineated using pegs and ropes at each segment of the stream, (three at each side of the stream). In vegetative sampling, a quadrant size of 2 meters by 3 meters was used. The sampling was done by counting the number of plants by species found rooted within the quadrant. All the species

encountered were identified using the services of experts and employing relevant flora. A species inventory of the plant species was also prepared. In other to quantify human interference on species abundance across and within the watershed sites, the frequency, relative frequency, density, relative density and species diversity were calculated.

Data Computation

In other to determine the species abundance and the diversity index of the watershed, the following computations were used:

- A) Density =
$$\frac{\text{total number of individual species}}{\text{total area sampled}}$$
- B) Frequency =
$$\frac{\text{number of times a species occurred}}{\text{total number of times searched for it}} \times 100$$
- C) Relative Density =
$$\frac{\text{density of individual species}}{\text{total densities of all the species}} \times 100$$
- D) Relative Frequency =
$$\frac{\text{frequency of individual species}}{\text{total frequencies of all the species}} \times 100$$

- E) Importance Value Index (ivi), that is summation of the relative density and the relative frequency
- F) Species Diversity = Shannon Weiners index of diversity
$$H^- = -\sum(pi) \times (\ln pi)$$

$$H_{\max} = \ln S$$

$$\text{Equatability} = \frac{H^-}{H_{\max}}$$

where H^- = Shannon index of diversity

S = number of species
 i-I = individual species to one
 pi = proportion of individual species
 In pi = natural log of the proportion of individual species

Statistical Analysis

In the analysis of the data, one-way, two-way and three-way

Analysis of Variance (ANOVA) were utilized.

RESULTS

Land Use Pattern of the Watershed

Table 1 shows the land use pattern of the watershed. The table indicates that lumbering of woods constitutes the most land use practice at the head segment of the watershed, lumbering of woods and

agricultural practices for the middle segment while agricultural and construction activity constitute the main activity at tail segment.

Table 1: Land Use Pattern of the Watershed

Segment	Aspect	Land Use Practices	Intensity of Practices
Head	Left	Lumbering of woods	Mild
	Right	Lumbering of woods and Agricultural	Mild
Middle	Left	(farming)	High
	Right	Lumbering of woods	High
Tail	Left	Agricultural (farming) and logging	Very high
	Right	Agricultural (farming) Construction and Agricultural (farming)	Very high

Species Abundance and Biodiversity Status of the Watershed

Tables 2, 3 and 4 show the species abundance status of the watershed by the different segments of the stream. The tables indicate that the tail segment of the

watershed was dominated by *Andropogon tectorum*, while the middle segment was dominated by *Panicum laxum* whereas the head segment was dominated by *Panicum*

maximum. In tables 5 and 6, the species abundance status of the watershed by aspect of the watershed is shown. The tables indicate that both aspect of the watershed was mainly dominated by *Andropogon tectorum*. In table 7, the species diversity of the watershed by segment and aspect of the stream is shown. The table indicates that the

species diversity of the watershed is higher at the head segment (0.81) and lower at the tail segment (0.72). With respect to aspect of the stream, the species diversity of the watershed is higher at the left aspect of the stream (0.68) and lower at the right segment of the stream.

Table 7: Species Diversity Status of the Watershed

Segment/Aspect	No of species	H'	H _{max}	Equitability
Segment				
Head	34	2.83	3.52	0.81
Middle	33	2.62	3.49	0.75
Tail	43	2.71	3.76	0.72
Aspect				
Left	64	2.82	4.16	0.68
Right	59	2.71	4.08	0.66

H' = Index Diversity

H_{max} = Maximum Equitability

Land Use Practices

Figure 1: The Species diversity in the watershed according to land use practices. Vertical lines indicate 95% confidence interval.

DISCUSSION

This study was conducted to assess the characterization and impact of human activities on a watershed (Imo Awka stream). The result of the study showed that nearly all part of the watershed have been disturbed through human activities ranging from wood lumbering, farming and construction. The less disturbed part of the watershed is the head segment and this was found to have higher species diversity. This supports the findings of [2] who observed that human activities of

deforestation and agriculture have reduced the diversity and structure of most watersheds. The study shows the land use practices of the watershed under study include farming, wood lumbering and construction. There are difference in the soil and species characterisation of watershed by segment, aspect and depth. The study shows that the land use practices in the watershed had negative effect on the species diversity.

RECOMMENDATIONS

Since in watershed, vegetation functions to slow off, reduce soil compaction, allow better percolation of rainfall into soils and groundwater, which creates better water storage for summer base flows, there is need for increased commitment in terms of management, planning and legislations that will aim at reducing

deforestation and excessive exploitation of watershed. There is also need to introduce and sustain reforestation practices in watershed so as to promote re-vegetation, protect the watershed soil and reduce shrinking of stream by sediments as a result of runoff.
